Programme: BSc Honours Degree in Psychology

Course Code: PLU 3303

Course Title: Motivation and Emotion

Number of pages in answer script: 05

Number of words in answer script: 1008

Student declaration*: I confirm that the submitted work is my own, the assignment was undertaken ethically, and the work does not include plagiarism*

Signature of student:

Student's surname with initials: Nagoda Gamage Sachini nadeesha Nethsarani

Student's Number: 525772803

National Identity Card number: 200572203435

Date: 15th Feb, 2026

Understanding Emotional Experience in Everyday Digital Life

Identification of the personal experience.

In the contemporary academic landscape, digital systems are not merely tools for information retrieval but are active environments that shape our emotional well-being. According to the course framework, emotional interactions within digital spaces are often influenced by perceived feedback and personal interpretation of situational outcomes (The Open University of Sri Lanka [OUSL], 2025). As a student of the BSc Honours in Psychology, I encountered a significant event while preparing a group presentation for the "PLU 3206 -Communication and Study Skills" course.

The incident- Our group selected motivation as the main topic. My assigned subtopic was "Psychological and Biological Drives". I had dedicated an entire day to intensive research, utilizing platforms such as Google Scholar, university e-learning databases, and AI tools like ChatGPT for brainstorming. I had meticulously organized my findings into an MS Word document and had over fifteen browser tabs open with highlighted articles. Due to a sudden power failure and a faulty laptop battery, my device shut down instantly. Upon restarting, I realized that the "Auto-Recover" function had failed to save my latest progress, I felt a deep sense of helplessness as I watched the black screen, realizing that hours of intense research had vanished in a second.

The Emotional Response: This technical failure immediately triggered a state of intense anxiety and panic. I felt a sudden surge in my heart rate and experienced shallow, rapid breathing. This was followed by a deep sense of frustration and hopelessness, as I perceived the lost time as an irreplaceable academic setback. The emotional distress was so profound that I withdrew from social interactions and lost my appetite for the remainder of the day, reflecting the deep "emotional connection" users form with their digital workplaces.

Theoretical Analysis of the Emotional Experience.

To critically analyze why this digital setback elicited such a powerful reaction, two foundational psychological theories are applied. Namely they are, The Schachter-Singer Two-Factor Theory and Lazarus's Cognitive-Mediational Theory.

Schachter-Singer Two- Factor Theory

Schachter and Singer (1962) proposed that emotion is a result of a two-stage process: psychological arousal followed by a cognitive label.

- **Application:** When the screen went black, my sympathetic nervous system triggered immediate physiological arousal- a racing hand and trembling hands. However, this physical state was ambiguous. My brain immediately sought an explanation in the environment and identified the "data loss" as the cause. I cognitively labeled this arousal as "extreme anxiety".
- **Critical analysis**: This theory highlights that my emotion was not a direct biological result of the power cut, but a result of how I interpreted my body's stress signals. Schachter and Singer (1962) suggest, if I had experienced the same racing heart while winning a game, I would have labeled it "excitement". In the digital context, the "threat" of a lost assignment led to a negative emotional label.

Lazarus's cognitive –Mediational Theory

Lazarus (1991) argues that cognitive assessment of a situation is the primary mediator that determines the emotional response, even before physiological arousal occurs.

- **Primary Appraisal**: My initial evaluation of the laptop shutdown was "Harm/Loss". I appraised the event as a significant threat to my academic goals, which directly triggered the feelings of frustration and sadness.
- **Secondary Appraisal**: After a period of distress, I moved into a secondary appraisal phase where I evaluated my coping resources. I realized that although the typed words were gone, the "knowledge" I had gained remained in my memory, and I could re-access the browser history.
- **Critical Analysis**

  This theory helps explain my emotional recovery. Once my appraisal shifted from "irreparable disaster" to a "manageable challenge", my emotional state changed from despair to focused motivation (Lazarus, 1991). This demonstrates that our emotions in digital spaces are highly dependent on our mental evaluation of the situation.

Practical and Ethical Management of Digital Emotions.

Managing digital stress requires a proactive approach to emotional regulation. Based on my experience and evidence- based psychological findings, the following strategies are suggested:

Developing Technical Resilience and "Safety Nets": The anxiety of data loss can be ethically managed by adopting technical habits that reduce "threat appraisal". Using cloud-based storage (e.g. Google docs, OneDrive) with real-time auto-saving features ensures that progress is never truly lost. Research shows that technical certainly significantly lowers the cortisol levels associated with digital work (OUSL, 2025)

.

Practicing Cognitive Reappraisal: When technical failures or errors occur, individuals should consciously "reframe" the situation. Instead of viewing a system crash as a personal failure, one should appraise it as a common limitation of current technology. This prevents the negative "cognitive labeling" described by Schachter and Singer, maintaining emotional stability.

Mindful Physiological Regulation: Recognizing the early signs of physiological arousal (e.g. increased heart rate) is crucial. Taking a physical break from the digital interface allows the autonomic nervous system to return to a baseline state. Stepping away to "calm the mind," as I did, is an evidence-based method to prevent emotional burnout and ensure a rational, ethical response to digital challenges.

Conclusion

My experience highlights the profound impact that digital systems have on human psychology. By applying the Schachter- Singer and Lazarus theories, it becomes clear that while technical failures are external, our emotional responses are governed by our internal appraisals and labels. By integrating technical safeguards with cognitive resilience, we can navigate the AI-integrated

academic world with greater emotional intelligence and stability. Moreover, this analysis emphasizes that ethical management of digital emotions requires a move beyond technical proficiency. It calls for a “digital emotional intelligence” where users recognize their bodily stress signals and consciously choose to reframe technical setbacks as manageable hurdles rather than existential threats. As AI and digital tools become more integrated into university life, the ability to maintain emotional stability through cognitive reappraisal will be a critical skill for students. By combining technical safety nets, such as cloud-based, auto-saving, with psychological self-regulation, we can foster a more resilient and ethically balanced interaction with technology. Ultimately, this journey from despair is a testament to the power of human cognition in mastering the emotional challenges of the digital age.
